

Modern Approaches to Prediction Modeling: Integrating AI and Machine Learning

Jessica Minnier, Ph.D.

Associate Professor, Biostatistics

OHSU-PSU School of Public Health

Knight Cancer Institute, Biostatistics & Data Science Shared Resource

OHSU AI Research Summit, 11/19/2025

The Evolution: From Association to Prediction

Traditional Association

Research Question:

"Is gene X associated with disease Y?"

Primary Goal:

Causal inference and etiologic understanding

Key Metrics:

P-values, Odds Ratios, Confidence Intervals

Prediction Modeling

Research Question:

"What is this specific patient's risk of disease Y?"

Primary Goal:

Accurate risk stratification and clinical decision support

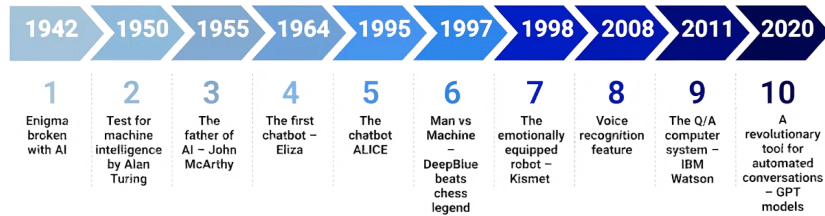

Key Metrics:

Accuracy, AUC, Calibration, PPV/NPV, NRI

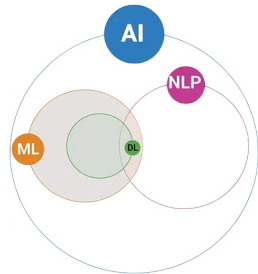

Today's data landscape is extraordinarily complex: EHR systems, multi-omics platforms, natural language processing, and advanced imaging all generate massive datasets. Our thesis: **The most powerful models integrate AI innovation with biostatistical rigor**, rather than relying on either approach alone.

The Evolving Synergy: Biostatistics Meets AI

Exploring the Historical Journey of Artificial Intelligence

Understanding the Relationship Between AI, ML, DL, and NLP

- AI is a broad field that includes anything related to making machines smart.
- NLP is the branch of AI focused on teaching machines to understand, interpret, and generate human language.
- ML is a subset of AI that involves systems that can learn by themselves.
- DL is a subset of ML that uses models built on deep neural networks to detect patterns with minimal human involvement.

1

Biostatistics Foundation

Provided a rigorous foundation for medical research, focusing on causal inference, hypothesis testing, and understanding disease mechanisms.

2

AI's Rise & Capabilities

Emergence grew with data volume and computational power, excelling in pattern recognition, predictive modeling, and complex data integration.

3

Synergistic Impact

Integrating biostatistics' rigor with AI's predictive power yields impactful advancements, leading to more comprehensive, reliable, and clinically actionable health insights.

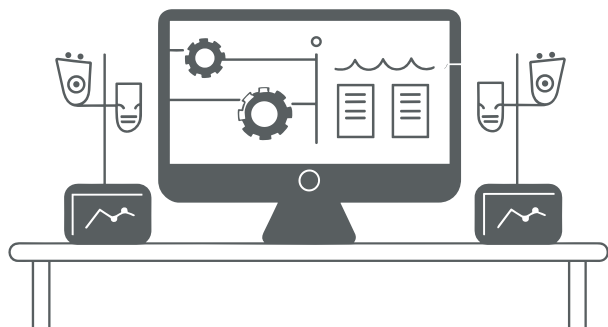

Alowais et al. Revolutionizing healthcare: the role of artificial intelligence in clinical practice. BMC Medical Education, 2023

Challenge #1: Defining Reliable Outcomes

Before building prediction models, we must establish trustworthy outcome labels.

Phenotypes derived from insurance billing codes often lack the precision needed for robust outcome definition, introducing measurement error and bias into prediction models.

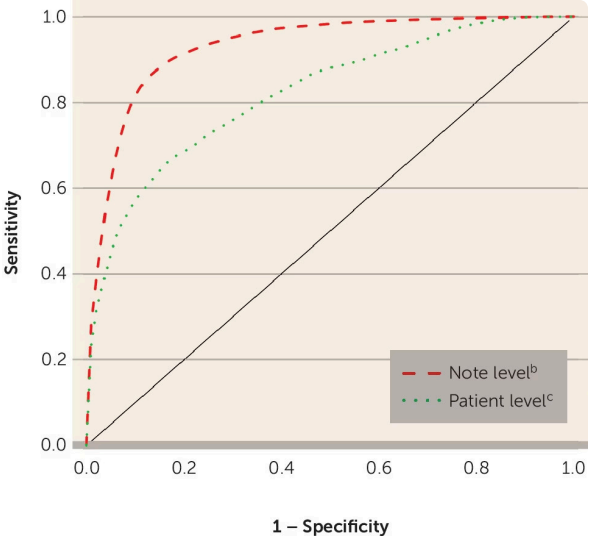

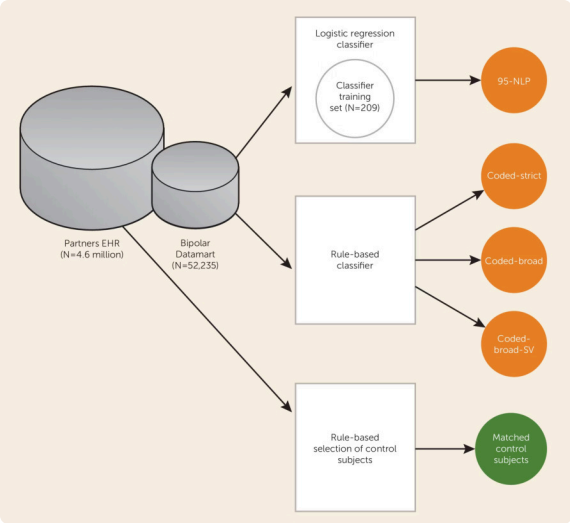

While a traditional gold standard, manual chart review is a labor-intensive process, creating a significant bottleneck that hinders research scalability and efficiency.

Machine learning and advanced statistical methods offer promising avenues to systematically define and validate reliable outcome labels, overcoming current limitations.

How can these innovative methods help us accurately define what we're trying to predict?

Case Study 1: Phenotyping Bipolar Disorder with Natural Language Processing

Research Goal	Methodological Approach	Validation Strategy
Identify Bipolar Disorder cases accurately within electronic health records	Adaptive LASSO (regularized regression) combined coded diagnostic data with NLP-extracted features from clinical notes	Compared algorithm predictions against gold standard SCID (Structured Clinical Interview) assessments
Clinical Impact		
Achieved PPV of 0.85, enabling creation of a reliable research cohort for subsequent genetic studies (4500 cases, 5000 controls)		

Case Study 2: Rheumatoid Arthritis with Limited Labels

The Innovation

Challenge: Automated feature selection with minimal labeled data

Solution: Unsupervised clustering on surrogate markers (ICD code counts) to generate "silver standard" labels, followed by Adaptive LASSO selection

Result: Achieved equivalent accuracy using only 50% of the labeled training data

Gronsbell, Minnier et al. Automated feature selection of predictors in electronic medical records data. Biometrics, 2018

❏ **Key Takeaway:** Machine learning and statistical methods are essential not just for prediction, but for defining the very outcomes we seek to predict.

Challenge #2: Integrating Complex, Multi-Modal Data

Once reliable outcomes are established, the next frontier involves modeling complex, high-dimensional predictors from diverse data sources. How do we effectively integrate genomic data, clinical variables, imaging features, and unstructured text?

Case Study 3: Non-Linear Genomic Risk Modeling

1

The Problem

Disease risk from thousands of SNPs exhibits non-linear relationships and gene-set structures that simple linear models cannot capture

2

The Solution

Adaptive Naive Bayes Kernel Machine (ANBKM)

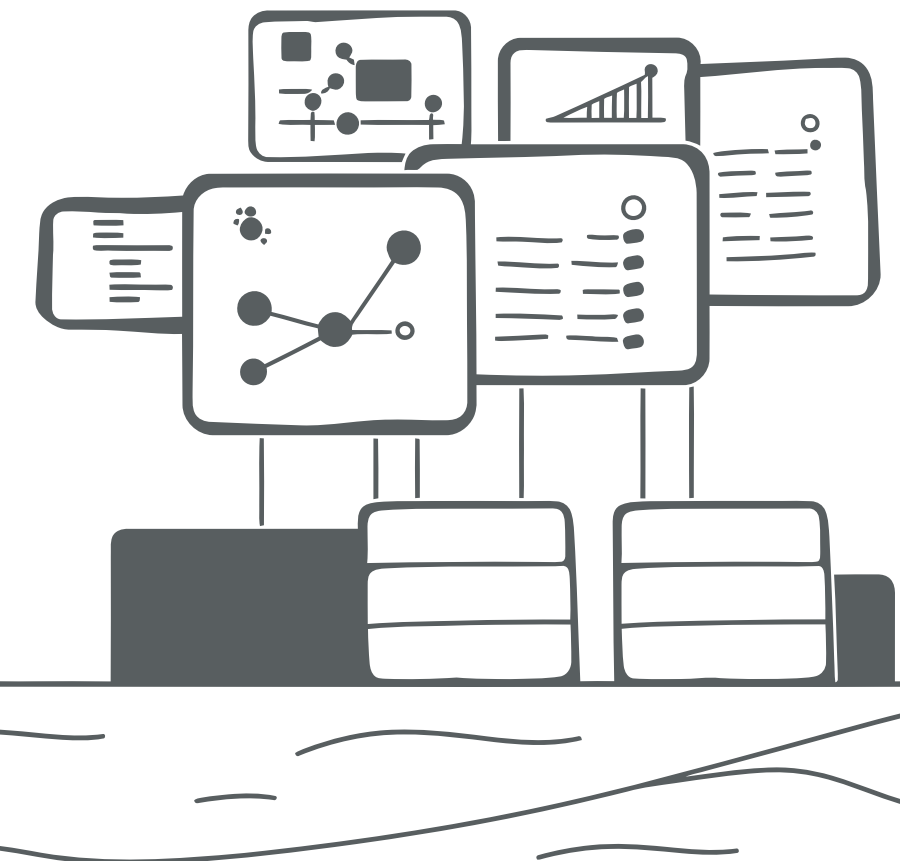

- Kernel Machine: Models complex, non-linear risk within gene-sets
- Naive Bayes + LASSO: Aggregates risk scores and selects informative gene-sets

3

The Advantage

Captures biological pathway structures while maintaining statistical interpretability and feature selection

Minnier et al. Risk classification with an adaptive naive Bayes kernel machine model. Journal of the American Statistical Association, 2015

Case Study 4: Ensemble Learning for Health Equity

Research Context

Goal: Infer Latino nativity status for health equity research using diverse EHR data sources

Data Sources:

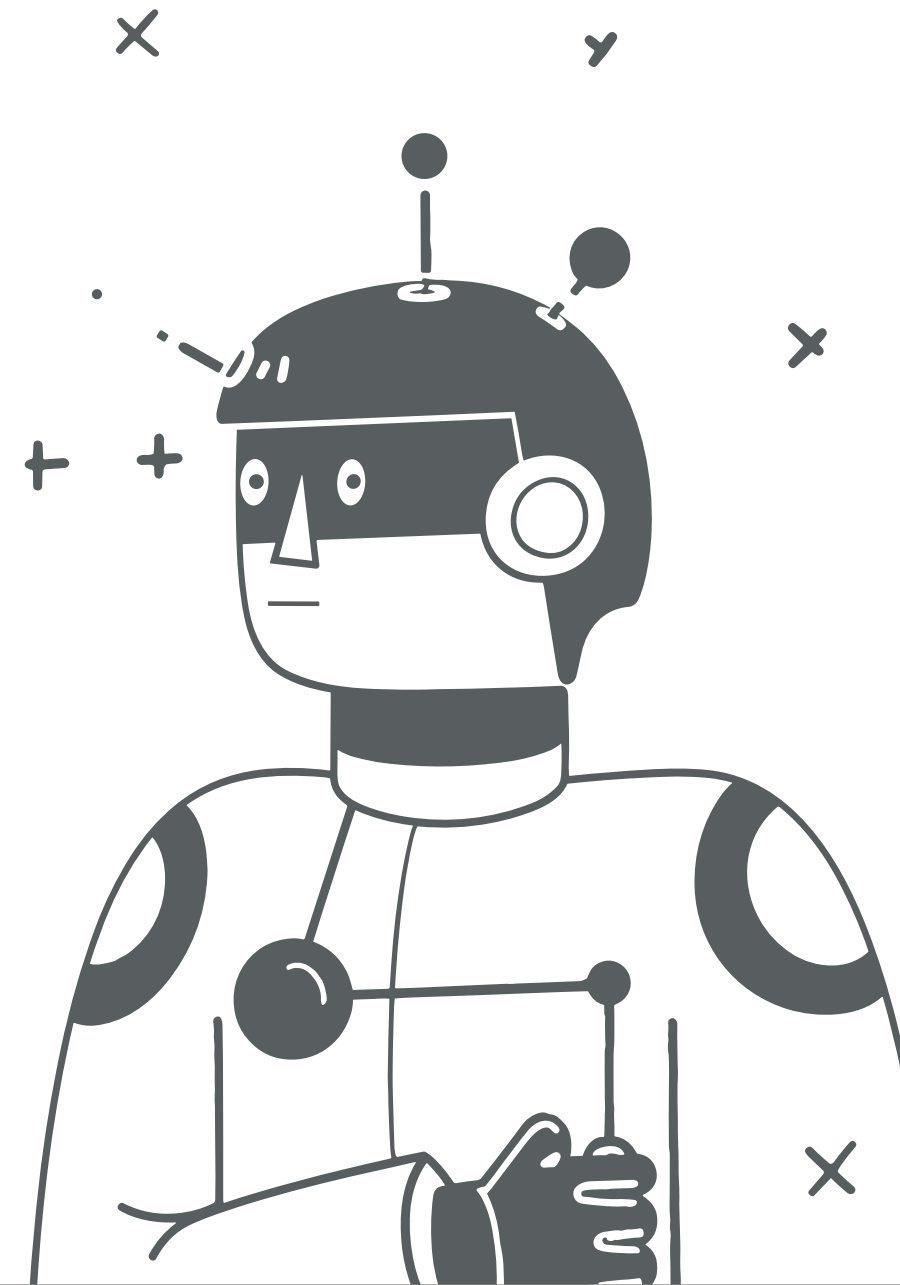

- Electronic health records
- Census tract information
- Surname-based indicators

Super Learner Approach

Combined multiple algorithms (Logistic Regression, Random Forest, Gradient Boosting) using optimal weighted averaging

Performance: Ensemble model achieved $AUC > 0.90$, substantially outperforming any individual algorithm

Marino, Minnier et al. Disaggregating Latino nativity in equity research using electronic health records. Health Services Research, 2023

The Frontier: Integrating "Black Box" AI into Prediction Models

The New Reality

FDA-authorized AI algorithms now provide powerful, stand-alone predictions for clinical use

The Biostatistician's Role

Our challenge: How do we rigorously integrate these AI tools with other predictive data sources?

The Opportunity

Create hybrid models that leverage AI strengths while maintaining statistical interpretability

Project Spotlight: VA Breast Cancer Risk Integration

We are developing the most comprehensive breast cancer risk model by integrating all available predictive data sources.

Clinical Data

Age, family history, reproductive factors, breast density, etc.

Genomics

Polygenic Risk Score (PRS) from genome-wide association studies

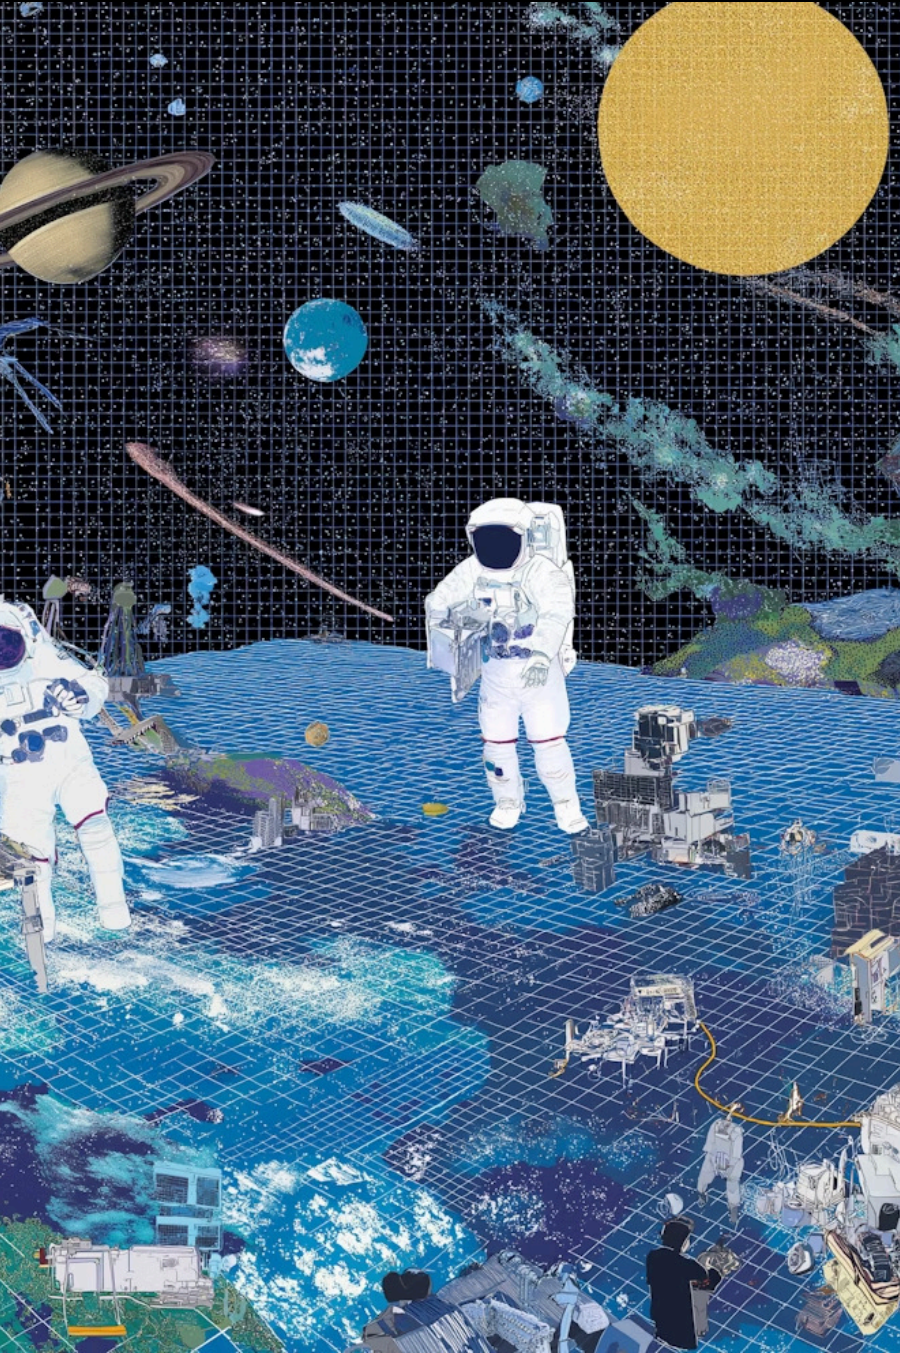

AI Imaging

"Clairity" algorithm score: deep learning model analyzing mammogram patterns

- ❏ **Statistical Innovation:** $\text{New_Risk_Model} = f(\text{Clinical_Data}, \text{PRS}, \text{AI_Score})$
Don't just compare AI to genomics—integrate them for maximum predictive power.

Clinical Impact: Identify high-risk women (elevated PRS + high AI score) for enhanced screening protocols and prevention interventions.

The Next Frontier: Large Language Models for Feature Extraction

Clinical notes contain rich information absent from structured fields: nuanced social determinants of health, detailed family histories, symptom severity trajectories, and treatment response patterns. LLMs represent the next generation of NLP, capable of extracting this complex information at scale.

Unstructured Data

Percentage of EHR data in free-text format

From Traditional NLP to LLM-Powered Extraction

Traditional NLP Approach

Our Previous Work:

- Bipolar Disorder: Keyword detection ("racing thoughts", "grandiosity")
- Rheumatoid Arthritis: Pre-defined term extraction
- Manual feature engineering required

Limitations: Labor-intensive, limited to predefined concepts

LLM-Powered Future

Emerging Capabilities:

- Automated reading of entire clinical narratives
- Complex concept extraction without manual rules
- Contextual understanding of medical language

Advantage: Scales to millions of notes, captures nuanced clinical patterns

Example Research Question: Can LLMs automate extraction of Bipolar subphenotypes (psychosis features, suicide attempts, age of onset) that we previously validated through manual review? If successful, this creates powerful new predictors for risk stratification models.

Key Conclusions: The Prediction Modeling Pipeline

1

1. Rigorous Phenotyping

Use ML and statistical methods to define reliable outcome labels when gold standards are limited

2

2. Flexible Modeling

Integrate diverse data types (clinical, genomic, imaging) using appropriate statistical and ML frameworks

3

3. AI Integration

Thoughtfully combine black-box AI predictions with interpretable statistical models for maximum clinical utility

4

4. Rigorous Validation

Assess calibration, clinical utility, and real-world performance—not just AUC

Critical Validation and Implementation Challenges

Beyond AUC: Comprehensive Validation

- **Calibration:** Do predicted 30% risks match observed 30% event rates?
- **Clinical Utility:** Does the model change clinical management decisions?
- **PPV/NPV:** What is real-world predictive performance in target populations?

Power Analysis and Grant Strategy

Calculate sample size requirements for *incremental value* metrics:

- Δ AUC improvement from adding AI component
- Net Reclassification Improvement (NRI)
- Feature variability estimation: Large sample sizes needed for stable estimation in models with many predictors
- Often requires simulation studies to demonstrate feasibility

Funding and Implementation

- **Funding Sources:** Pursuing NIH and VA grants for validation and implementation
- **Key Requirements:**
 - Access to images and/or non-coded text fields
 - Ability to implement AI models in clinical workflows
 - Clinical trial studies examining utility of screening or early diagnosis
